

## Microstrip Patch Antenna

Microstrip patch antennas are among the most popular antennas, used in various application areas. Model building for this type of antennas can be done in two ways: in WIPL-D general-purpose 3D modeler and in the tool specialized for printed structures, AW Modeler. A simple microstrip patch antenna is simulated here. The simulated results are verified with measurements performed by WIPL-D staff.

The **software predicted** the resonance at **1.905 GHz**, while **measurements** pointed to **1.906 GHz**. The simulated bandwidth is **19.35 MHz** while the measured one is **19.3 MHz**. The relative discrepancy is **0.05 %** for resonant frequency and **0.25 %** for bandwidth.

The prototype (Fig. 3) is fed from the back side, by a probe which is connected to coax line via standard SMA connector.

Figure 3. Front Side of Antenna Prototype

Figure 2. Coaxial Feed of the Antenna

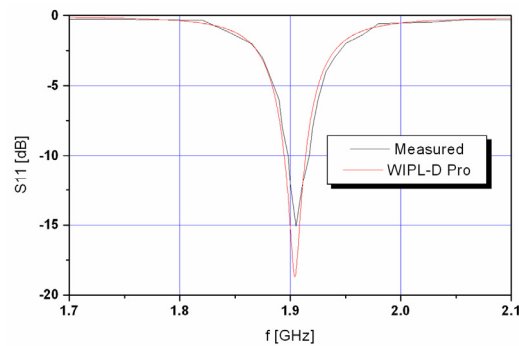

Figure 4. S11 of the coaxially fed patch antenna

The antenna is printed on RT Duroid 5880 substrate of height 1.5748 mm and of complex permittivity  $2.2(1-j 0.0004)$ . The model is made on a finite substrate and over finite ground plane (Fig. 1). The copper conductor is taken with finite conductivity of  $\sigma = 19$  MS/m, to account for surface roughness. The antenna is fed by a probe that is extended to a coaxial line. A part of the coaxial line is included in WIPL-D model to simulate effects of realistic coaxial feed (Fig. 2).

The simulated and measured S-parameters (Fig. 4), and radiation pattern in E-plane (Fig. 5) agree excellently.
